## Sentiment Analysis - Elon Musk dataset

# 1. Data analysis

## Analysis related to time of publishing tweets

- The highest number of tweets was posted between 5 PM and 11 PM, likely because we are analyzing Monday and Tuesday times when people are typically back from work.
- There are no major differences in sentiment distribution across dayparts, although negative tweets are more frequent at night.
- In this dataset, the number of tweets on Tuesday was twice as high as on Monday. It's unclear whether this reflects a specific pattern. • There are no significant differences in sentiment distribution between the two weekdays, although slightly more positive tweets were posted on Monday.

weekday\_name

## Analysis related to number of followers and tweet structure

Monday

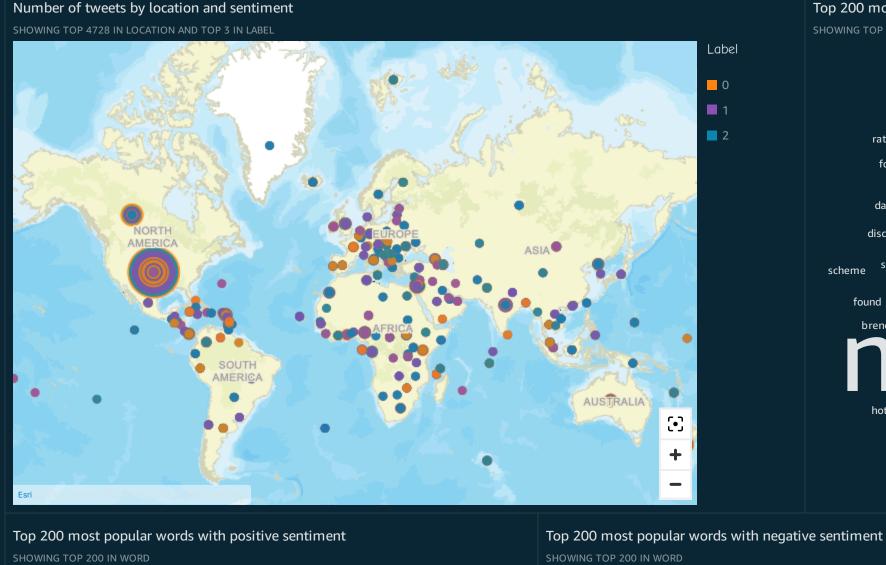

• There are no major differences in the number of followers based on sentiment, although positive tweets tend to come from users with slightly more followers.

Tuesday

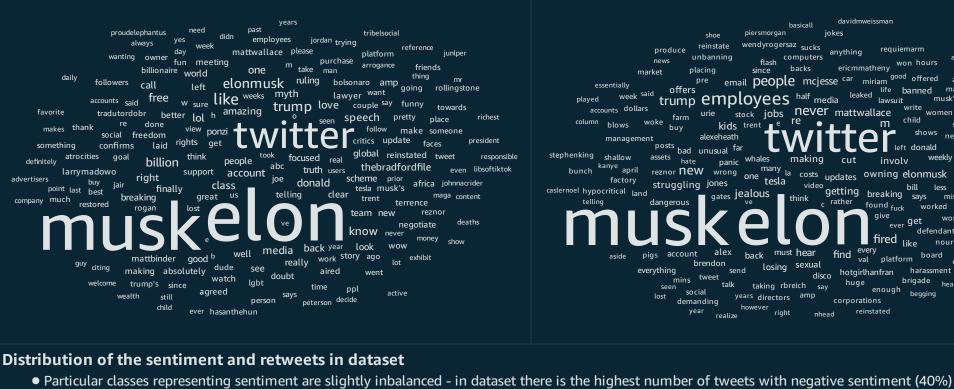

- Tweets labeled as negative tend to be longer. Neutral tweets are slightly shorter, and positive ones are in between.
- When analyzing the number of words, the pattern is similar to tweet length, although the differences are less pronounced.

positive\_pred

Tuesday

### • There is only 87k unique tweets, so around 27% of whole dataset, the rest 73% these are retweets. • Some retweets were published over 7.5k times, which means that random data splitting could lead to data leakage during model building. That's why I decided to split the data chronologically (based on time).- in the test set there is 20% of the

- most actual tweets; there is still a risk of appearing retweets, but smaller.

### Summary of the model performance • The best result gave Logistic Regression with features based on tweet text.

### • The model correctly predicts sentiment in most cases, reaching 88% accuracy. • It performs best on neutral tweets, with an accuracy of 90%.

• The model makes the most mistakes between positive and neutral tweets, which are sometimes hard to distinguish.
